

EXPERIMENT NO. 1

AI-BASED EVENT REGISTRATION AND MANAGEMENT USING LOW-CODE DEVELOPMENT

Thaneshwar M

240701561

1. Aim

To design and implement an event registration and management application using a low-code platform, Zoho Creator, by creating a registration form, report, automated confirmation workflow, and QR-code based event verification.

2. Traditional Application Development vs Emerging Low-Code Application Development

Traditional application development involves manually designing the user interface, application logic, database, validation, testing, deployment, and maintenance using programming languages and development frameworks. It provides high control and customization, but implementation of common features generally requires more coding effort and development time.

Low-code application development uses visual builders, drag-and-drop components, reusable features, workflows, reports, templates, and integrations. In this experiment, Zoho Creator was used to build the Event Registration System with minimal manual programming while still supporting data collection, automation, reporting, and QR-code generation.

3. Benefits and Challenges in Low-Code

Benefits include faster application development, reduced repetitive coding, easy form and report creation, workflow automation, rapid modification of application components, built-in data management, and support for QR-code based verification. These features make low-code suitable for event registration and other business process applications.

Challenges include platform dependency, limitations for highly specialized customization, the need for proper security and access control, testing and maintenance requirements, and possible vendor lock-in. Low-code reduces manual coding but does not remove the need for software engineering practices.

6. Comparison of Existing Low-Code Platforms (Tabulation)

Platform	Key Features	Suitability for Event Registration
Zoho Creator	Forms, reports, workflows, templates, automation and QR-code fields.	High – used in this experiment for registration, reporting, email automation and QR verification.
Microsoft Power Apps	Visual app development with business process automation and Microsoft integrations.	High – suitable for enterprise registration and workflow applications.
Mendix	Visual development, reusable	High – suitable for structured

	components and enterprise application support.	business applications.
OutSystems	Enterprise low-code development with extensive customization and integration options.	High – useful for larger and more complex applications.
AppSheet	Data-driven applications, forms and workflow automation with low-code configuration.	High – suitable for simpler registration and data collection systems.
Salesforce Platform	Low-code tools integrated with CRM, automation and business data.	Medium/High – useful when registration is connected to Salesforce-based processes.
Bubble	Visual web application development with workflows and database features.	Medium – suitable for web-based custom registration applications.

7. Result

The Event Registration and Management System was successfully developed using Zoho Creator. The application included a participant registration form, an organized report, a successful form-submission workflow, confirmation email automation, and QR-code generation for registered participants.

The experiment demonstrated that low-code development can reduce repetitive programming effort and accelerate application delivery. Zoho Creator was effective for this assignment because forms, reports, workflows, and QR-code functionality could be configured visually. The completed application provides a practical solution for collecting registrations and supporting event verification.
